DM17-0780
Dynamic Design Analysis

**Problem:** Increasingly, software systems are composed at runtime. Yet, the impact of runtime composition on design quality is unknown. Static analysis has shown that design flaws make bugs and security vulnerabilities more likely, but does not detect the effect of dynamic dependencies.

**Solution:** A technique to detect such flaws, either fully automatically (where possible) or semi-automatically (where necessary).
Main Technical Challenges

1. Detecting dynamic dependencies (DDs).
2. Determining whether DDs create new kinds of architectural flaws.
3. Determining the consequences of DD-induced design flaws.
4. Proposing refactorings to remedy these flaws.
Thrust 1: Recovering Android App Interactions

APK Files → Model Extractor → App Model

Acme Template → Template Engine

Android Family → App Architecture

Acme Studio → Recovered System Architecture
Thrust 1: Recovering Android App Interactions

Conformance Analysis Using ACME:

Many security violations come from data flows between components
Some of these can be checked via first order predicate logic

- E.g., Annotate applications with trust levels and check information disclosure

\[
\text{forall } a1 : \text{! AndroidApplicationGroupT in self.GROUPS} \mid \text{forall } a2 : \text{! AndroidApplicationGroupT in self.GROUPS} \mid ((a1 != a2) -> (forall src in /a1/MEMBERS://ApplicationElement/PORTS://IntentBroadcastPortT | forall activity :! ActivityComponentT in a2.MEMBERS | forall tgt :! IntentReceivePortT in activity.PORTS | ((\text{connected}(src, tgt) and \text{contains}(src.action, activity.intentFilters)) \rightarrow a1.\text{trustLevel} \leq a2.\text{trustLevel})));
\]

Apps cannot communicate implicit intents to apps that have a lower trust level
Thrust 1: Recovering Android App Interactions

Model Checking with COVERT

Given Android specification $S$, app specifications $M$, and vulnerability assertion $P$, assert whether $M$ does not satisfy $P$ under $S$. 

$M \models S \land \neg P$
Thrust 2: Discovering Dependencies by Tracking Issues

Observation: Dynamic dependencies are often revealed in co-change relationships.

Operationalization:

- We can mine issue repositories and revision-control systems to discover these "hidden" relationships.
- We can leverage this information to find architectural flaws among related sets of files.
- We have created a new architectural view, called "Issue Space", a sequence of Snapshots (Si):

\[
\text{IssueSpace} = \langle S_1, S_2, \ldots, S_n \rangle
\]

where n is the # of commits in the revision history to address the issue
Thrust 2: Discovering Dependencies by Tracking Issues

• Each snapshot is a 2-element tuple:

\[ Sr = \langle G, t \rangle \]

where \( t \) is the time-stamp when a commit is made to address the issue, and \( G \) is a graph: \( \langle V,E \rangle \)
where \( V \) is the set of files involved in the commit at time \( t \).
Thrust 2: Discovering Dependencies by Tracking Issues

- Example: Apache Cassandra, Issue 436

commit4

Diagram with dependencies between classes and issues.
Consequences:

• we have shown that when a system has files revised in many different issues—what we call a *hotspot*—these "shared" files are *connected*

• and that these hotspots almost always have design flaws leading to bugs, security flaws, and maintenance problems

• thus they should be analyzed and refactored
Thrust 2: Discovering Dependencies by Tracking Issues

- Example: Apache Cassandra
Thrust 2: Discovering Dependencies by Tracking Issues

- Example: Apache Pig
Conclusions and Future Work

By considering dynamic information we can find design flaws, and hence locate the root causes of bugs more quickly.

This information is not available solely via static analysis; dynamic dependencies must be considered.

These flaws are the roots of technical debt.

In our future work we are examining the relationship between such design flaws and security bugs.
