1 Introduction

Serpent is a user interface management system (UIMS) that supports the development and execution of a user interface of a software system. Serpent supports incremental development of the user interface from the prototyping phase through production to maintenance or sustaining engineering. Serpent encourages a separation of functionality between the user interface functional portions of a software system. Serpent is also easily extended to support additional user interface toolkits.

1.1 This Manual

This manual describes how to develop applications using Serpent. Readers are assumed to have read and understood the concepts described in the Serpent Overview, as well as to have had experience using the C programming language.

1.1.1 Organization

The contents of this guide include:

- **Introduction** and **Overview**. This chapter provides a general description of the role of an application in a software system developed with Serpent. It also describes a conceptual framework for application development.

- **Specifying the Contract**. This chapter describes the tasks necessary to define the type, structure and values of data to be shared between an application program and Serpent and to establish runtime communications with Serpent.

- **Modifying Information**. This chapter describes the tasks necessary to add, modify or remove information to/from the Serpent shared database.

- **Retrieving Information**. This chapter describes the tasks necessary to define and retrieve changes to information from the Serpent shared database.

- **Finishing the Application**. This chapter describes the finishing touches that should be applied to the application, including error checking and exception handling.

- **Testing and Debugging**. This chapter describes utilities available to assist in the testing and debugging of the application.

- **Appendix A: Data Structures**. This appendix is a complete reference of all the constants, types, routines, and other data structures available to Serpent application developers using the C programming language.
Introduction

- **Appendix B: Routines.** This appendix is a complete reference of all the routines available to Serpent application developers using the C programming language.

- **Appendix C: Commands for Testing Serpent Applications and Dialogues.** This appendix is a reference of commands available to Serpent application developers from the operating system.

- **Appendix D: Spider Example.** This appendix is a complete application example, developed in the C programming language.

### 1.1.2 Typographical Conventions

- **Code examples**  
  **Courier typeface**

- **Code directly related to text**  
  **Bold, courier typeface**

- **Variables, attributes, etc.**  
  **Courier typeface**

- **Syntax**  
  **Courier typeface**

- **Warnings and cautions**  
  **Bold, italics**

### 1.2 Other Serpent Documents

The purpose of this guide is to provide the information necessary to develop Serpent applications. The following publications address other aspects of Serpent.

*Serpent Overview*
Introduces the Serpent system.

*Serpent: System Guide*
Describes installation procedures, specific input/output file descriptions for intermediate sites, and other information necessary to set up a Serpent application.

*Serpent: Saddle User’s Guide*
Describes the language that is used to specify interfaces between an application and Serpent.

*Serpent: Dialogue Editor User’s Guide*
Describes how to use the editor to develop and maintain a dialogue.
Introduction

*Serpent: Slang Reference Manual*
Provides a complete reference to Slang, the language used to specify a dialogue.

*Serpent: Ada Application Developer’s Guide*
Describes how the application interacts with Serpent. This guide describes the runtime interface library, which includes routines that manage such functions as timing, notification of actions, and identification of specific instances of the data.

*Serpent: Guide to Adding Toolkits*
Describes how to add user interface toolkits, such as various Xt-based widget sets, to Serpent or to an existing Serpent application. Currently, Serpent includes bindings to the Athena Widget Set and the Motif Widget Set.
Introduction

The following figure shows Serpent documentation in relation to the Serpent system:
2 Overview

A main goal of Serpent is to encourage the separation of a software system into an application portion and a user interface portion to provide the application developer with a presentation-independent interface. The application portion consists of those components of a software system that implement the “core” application functionality of a system. The user interface portion consists of those components that implement an end-user dialogue. A dialogue is a specification of the presentation of application information and end-user interactions.

During the design stage, the system designer decides which functions belong in the application component and which belong in the user interface component of the system.

2.1 Serpent Architecture

Serpent is implemented using a standard UIMS architecture. This architecture (see Figure 2-1) consists of three major layers: the presentation layer, the dialogue layer, and the application layer. The three different layers of the standard architecture are viewed as providing differing levels of end-user feedback.
Figure 2-1  Serpent Architecture

The presentation layer consists of various input/output toolkits that have been incorporated into Serpent. Input/output toolkits are existing hardware/software systems that perform some level of generalized interaction with the end user. Serpent is being distributed with an interface to the X Window System, Version 11. Other input/output toolkits can be integrated with Serpent. See *Serpent: Guide to Adding Toolkits* for a discussion of how this can be accomplished.
One way of viewing the three levels of the architecture is the level of functionality provided for user input. The presentation layer is responsible for lexical functionality, the dialogue layer for syntactic functionality, and the application layer for semantic functionality. In terms of a menu example, the presentation layer has responsibility for determining which menu item was selected and for presenting feedback that indicates which choice is currently selected. The dialogue layer has responsibility for deciding whether another menu is presented and presenting it, or whether the choice requires application action. The application layer is responsible for implementing the command implied by the menu selection.

The end user interface for a software system is specified formally as a dialogue. The dialogue is executed by the dialogue manager at runtime in order to provide an end user interface for a software system. The dialogue specifies both the presentation of application information and end user interactions. The Serpent dialogue specification language (Slang) allows dialogues to be arbitrarily complex.

The application provides the functional portion of the software system in a presentation-independent manner. It may be developed in C, Ada, or other programming languages. The application may be either a functional simulation for prototyping purposes or the actual application in a delivered system. The actions of the application layer are based upon knowledge of the specific problem domain.

2.2 Shared Database

Serpent provides an active database model for specifying the user interface portion of a system. In an active database, multiple processes are allowed to update a database. Changes to the database are then propagated to each user of the database. This active database model is implemented in Serpent by a shared database that logically exists between the application and I/O toolkits. The application can add, modify, query, or remove data from the shared database. Information provided to Serpent by the application is available for presentation to the end user. The application has no knowledge of the presentation media or user interface styles used to present this information.

Information in the shared database may be updated by either the application or I/O toolkits. Figure 2-2 illustrates the use of the shared database in Serpent.
Serpent allows the specification of dependencies between elements in the shared database in the dialogue. These dependencies define a mapping among application data, presentation objects, and end user input. The dialogue manager enforces these dependencies by operating on the information stored in the shared database until the dependencies are met. Changes are then propagated to either the application or the I/O toolkits as appropriate. See the *Serpent: Slang Reference Manual* (CMU/SEI-91-UG-5) for a further discussion.

The *type* and *structure* of information that can be maintained in the shared database is defined externally in a *shared data definition file*. This corresponds to the database concept of *schemas*. A shared data definition file is required for each application.
A shared data definition file consists of both aggregate and scalar data structures. Top-level data structures become *shared data* elements that may be instantiated at runtime. Nested data structures become components that are considered part of the shared data element. Serpent does not allow nesting of records.

**Figure 2-3  Shared Data Instantiation**

It is possible to define multiple instances of a single shared data element. Shared data elements are instantiated by specifying the element name. Each *shared data instance* is identified by a unique *ID*. IDs must be maintained by the application to identify shared data instances when multiple instances of a single shared data element exist. Figure 2-3 provides an illustration of shared data instantiation.

Since the dialogue manager, the application, and any toolkits participating in a particular execution of Serpent are separate system processes that use the shared database, they can potentially modify the database concurrently, possibly compromising the integrity of the database. This problem is solved in Serpent through the use of database concurrency control techniques. Updates to the Serpent shared database are packaged in transactions. Transactions are collections of updates to the shared database that are logically processed at one time. Transactions can be *started*, *committed*, or *aborted*. A transaction which has been started but neither committed nor aborted yet is said to be *open*. Multiple transactions may be open at the same time. Committing a transaction causes the updates to be made to the shared database. Aborting a transaction causes termination of the transaction without any update of the shared database.
Overview

**Communicating with Serpent**

The application communicates with Serpent using the shared database model described earlier in this document. Information added to shared data is available to be presented to the end user by the dialogue. Changes to application data are automatically communicated back to the application.

2.3 **Application Development**

The application, or non-user interface portion of the system, provides the “core” functionality of a software system developed using Serpent. The application can be written in Ada, C, or other programming languages and can be either a simulation or an actual application.

An application may only add information to shared data or it may only retrieve information from shared data. For example, an application that monitors and displays the status of a computer network may only need to add information to shared data to update the display. An application such as an automatic teller machine (ATM) might only need to retrieve data from the user interface.

All transactions to and from the application are handled explicitly in the application using the routines and data structures available in the Serpent application interface. This document describes the usage and definitions of these routines and data structures.

**Error Checking and Recovery**

Each routine in Serpent sets status on exiting. It is the responsibility of the application developer to check this status to perform appropriate error recovery. Serpent provides routines to both check and print the status.

**Testing and Debugging**

Serpent provides a record/playback feature that can be used in testing and debugging. Transactions between the application and dialogue manager or between the dialogue manager and the various toolkits can be recorded, then played back at a later time. This is useful in isolating problems or in performing regression/stress testing of an application, dialogue, or toolkit.
Spider Example

The spider application is an example of an application system developed using Serpent. Figure 2-4 is an illustration of a “spider chart” display that is one possible end-user interface for the application.

Adapted from a command and control application, the spider application monitors and displays the status of various sensor sites and their associated communication lines to the two correlation centers (Figure 2-4).

Figure 2-4 Spider Chart Display
Overview

The columns of rectangular boxes on the right and left sides of the spider chart display (for example, GS1, GS2) represent sensor sites. The rectangles in the middle of the display represent the correlation centers that collect information from the sensors. Each sensor site communicates with both correlation centers; this is represented by the duplication of sensor site boxes on both the right and left sides of the display. The lines represent communication lines between the sensor sites and the correlation centers. The status of sensors is represented by the shading of the rectangles. On a color display, the status would be represented using different background colors.

An operator may display detailed information concerning a sensor site by selecting a sensor site box corresponding to that sensor. This causes a detailed window to appear, displaying the status of the sensor, the date and time of the last message, the reason for outage (RFO) and the estimated time to returned operation (ETRO). These fields may be modified by the operator. Sensors may be in one of three states: operational, impaired, or down. For sensors that are not fully operational (i.e., the status is yellow) the ETRO is displayed to the outside of the sensor site box. ETROs are also displayed over communication lines that are not fully operational. The operator may also dynamically reconfigure the network by adding/deleting sensors to/from the network.

1The capability of dynamically reconfiguring the network does not exist in the spider chart example distributed with Serpent Version 1.0.
3 Specifying the Contract

The first step in creating a software system using Serpent is to apportion system functionality between the dialogue and the application. This involves creating a contract between the two components: defining the type and structure of information to be communicated, or shared, between the two components; establishing the range of values of this data; and establishing runtime communication between the components.

3.1 Defining Shared Data

Shared data is information that is communicated or shared between the application and dialogue. Defining shared data involves two steps:

1. Create the shared data definition file.
2. Run the created file through the Saddle processor.

The following is a brief description of each of these two steps. The *Serpent: Saddle User’s Guide* contains a more complete description of both these steps.

**Step 1: Create the shared data definition file.** The shared data definition file defines the type and structure of information that can be shared between the application and dialogue. The shared data definition is specified in Saddle. By convention, the file is given the name of the application, followed by the extension .sdd.

Example 3-1 is an example of a shared data definition file for the spider application. The content of the shared data definition file is independent of the implementation language used. Note that these shared data record templates contain only information to define the application objects; they do not specify how the information is presented to the end user.

```plaintext
<< spiderA >>
spider: shared data

sensor_sdd: record
    site_abbr: string[3];
    status: integer;
    site: string[32];
    last_message: string[8];
    rfo: buffer[32];
    etro: string[8];
end record;

cc_sdd: record
    name: string[3];
    status: integer;
end record;

communication line_sdd: record
```
Specifying the Contract

```plaintext
from_sensor: id of sensor_sdd;
  to_cc: id of cc_sdd;
  etro: string[8];
  status: integer;
end record;
end shared data;
```

Example 3-1  Spider Shared Data Definition File

The file shown in Example 3-1 contains definitions for the data shared between the application and the dialogue for the spider application. The first line of the file contains the name (and possible path information) of the executable image of the application. This application is automatically executed by the Serpent command at runtime. (Serpent: System Guide contains a complete explanation of this process.) The three shared data record templates define the type and structure of the sensor, correlation center, and communication line application objects.

Step 2: Run the created file through the Saddle processor. Once the shared data has been defined in the file, it can be processed by Saddle to generate a C language header file. This file will have the same name as the shared data definition file with a different extension. For example, the shared data file spiderA.sdd will generate the header file spiderA.h. This header file can then be included in the C application and used to declare local variables of the shared data types. The C header file generated by running the shared data definition file shown in Example 3-1 through the Saddle processor is illustrated in Example 3-2.

```c
#define MAIL_BOX  "sss_mailbox"
define ILL_FILE  "sss.ill"

typdef struct {
    char site_abbr[4];
    int status;
    char site[33];
    char last_message[9];
    char rfo[33];
    char etro[9];
} sensor_sdd;

typdef struct {
    char name[4];
    int status;
} cc_sdd;

typdef struct {
    id_type from_sensor;   /*ID of sensor */
    id_type to_cc;         /*ID of correlation center */
    char etro[9];
    int status;
} line_sdd;
```

Example 3-2  C Language Header File
In Example 3-2, the first two lines in the file define two well-known constants: \texttt{MAIL\_BOX} and \texttt{ILL\_FILE}. These constants will be used in initializing Serpent. The three structures correspond to the record templates defined within the shared data definition file.

### 3.2 Data Types and Values

One output of processing the shared data definition file through the Saddle processor is a C header file containing corresponding C structures for the shared data records. These C structures can be used to declare local variables that correspond in size and structure to shared data records or used as casts. Components of shared data records can be declared as any of the following types: boolean, integer, real, string, ID or buffer. The C structures generated from these declarations depend on the type of the components. Example 3-3 is unrelated to the spider example used throughout this guide but includes a description of a shared data record that contains an example of each type of component.

```c
employee_sdd: record
  name: string[32];
  salary: integer;
  exempt: boolean;
  experience: real;
  job_desc: buffer;
  self: id of employee_sdd;
end record;
```

**Example 3-3  Shared Data Definition**

Example 3-4 shows the C structure that is generated when the \texttt{employee\_sdd} record is processed by Saddle processor.

```c
typedef struct {
  char name[33];
  int salary;
  boolean exempt;
  double experience;
  buffer job_desc;
  id_type self;
} employee_sdd;
```

**Example 3-4  Generated C Structure**

Although each shared data component is now represented using a C language specific type, there is still a Serpent data type associated with each of them. The Serpent data type can be determined at runtime using the \texttt{get\_shared\_data\_type} function illustrated in Example 3-5. The \texttt{serpent\_data\_type} is an enumeration of the different Serpent data types and is defined in Appendix A.
Specifying the Contract

serpent_data_type type;
/*
 ** Get the Serpent type of the employee record salary
 ** component.
*/
type = get_shared_data_type("employee", "salary");

Example 3-5  Serpent Data Type

Shared data values specified as strings in the shared data definition file are represented by character arrays in the C header files generated by the Saddle processor. It is therefore not necessary to allocate heap memory for these strings, although it is necessary to use the Unix strcpy function (see Example 3-6) or a similar utility to copy data into the character array.

/*
 ** Declare a local shared data variable.
*/
employee_sdd employee;
/*
 ** Use strcpy to assign a string value.
*/
strcpy (employee.name, "Harry Alter");

Example 3-6  Assigning Values to String Components

Shared data components of type integer, boolean, real, or ID can be assigned directly to C language variables. IDs are returned from a number of Serpent routines and are id_type. Saddle integers and booleans are actually of C type int and Saddle reals are actually of C type double. (See Example 3-7.)

#define false 0
#define true 1

/*
 ** Integer, boolean, real or id components can be set
 ** directly.
*/
employee.salary = 45000;
employee.exempt = false;
employee.salary = 3.2;

Example 3-7  Assigning Values to Integer, Boolean, Real or ID Components

Buffer is the only dynamic shared data type in that neither the size nor the type of the information is predefined. Example 3-8 describes the buffer structure. Buffer type is required and specifies the type of information stored in the buffer. Buffer length is the size in bytes of the data and is required even if the data is of a well known type (i.e., integer). Buffer body is a pointer to the actual data. The space used to maintain this data is not part of the buffer structure and must be managed by the user.
Buffers can be used to:

- Share untyped, contiguous data.
- Share large amounts of contiguous data (i.e., large strings).
- Provide variant records.

Example 3-9 contains the example of the `employee.site` buffer being used as a string.

```
/*
 ** This buffer is being used as a string.
 */
employee.job_desc.type = serpent_string;
employee.job_desc.length = strlen("Look busy") + 1;
employee.job_desc.body = malloc(employee.job_desc.length);
strcpy(employee.job_desc.body, "Look busy");
```

### Example 3-9 Assigning Values to Buffer Components

Shared data values can also be undefined. All uninitialized components of a shared data record instance created using the `add_shared_data` function are initialized by Serpent to be undefined. On the other hand, components of a local, shared data variable have whatever values are left by the system—most likely zeros. If this structure is used to initialize the shared data instance (with the `add_shared_data` or `put_shared_data` routines), all the components of the instance are initialized with these values. Components of local, shared data variables can be explicitly set to undefined using the `set_undefined` routine illustrated in Example 3-10. The `is_undefined` function can be used to determine if a component value is undefined.

```
/*
 ** The set_undefined function is used to set the value of
 ** a component to undefined.
 */
set_undefined(serpent_buffer, &employee.job_desc);
```

### Example 3-10 Setting Component Values to Undefined
3.3 Initialization and Cleanup

The first task of any Serpent application is to initialize the system. Serpent initialization establishes communication between the application and the dialogue. The final application task is to clean up the Serpent system environment before exiting. The code segment from the spider application shown in Example 3-11 illustrates the basic operations necessary for Serpent initialization and cleanup.

```c
#include "serpent.h" /* serpent interface definition */

main() {
  serpent_init(MAIL_BOX, ILL_FILE);
  serpent_cleanup();
}
```

**Example 3-11 Serpent Initialization**

**Specification Steps:**

1. **Include Serpent header file.** The `serpent.h` file contains the external definition for the Serpent interface.

2. **Initialize Serpent.** The `serpent_init` procedure is used to initialize Serpent. It takes as parameters the `MAIL_BOX` and `ILL_FILE` constants generated by the Saddle processor. This procedure establishes communication between the application and the dialogue manager.

3. **Clean up.** The `serpent_cleanup` routine must be invoked before exiting the application. It is important to complete this step to release allocated system resources.
4 Modifying Information

The application can add, change, or remove information to and from the shared database using the transaction mechanism described in the introductory chapter of this document. Together, these are considered modifications to the shared database. The collection of application data in the shared database is known as the *view*. This is the information that is available to the dialogue writer to be presented to the end user. The view can be modified by either the application or the dialogue.

4.1 Sending Transactions

Before information can be modified in the shared database, it is necessary to start a transaction. All modifications to the shared database must be performed as part of a transaction.

It is possible to have multiple transactions open at one time. Each transaction has a unique transaction handle. Every operation performed on or to a transaction must specify this transaction handle.

The actual change to the shared database does not occur until the transaction is committed. Up to this point it is also possible to roll back the transaction so that none of the changes to shared data occur.

The code segment from the spider application in Example 4-1 shows the operations necessary for sending transactions. Code and comments directly related to the task are emphasized in bold type.

```c
#include "serpent.h"  /* serpent interface definition */
main() {
  transaction_type transaction;  /* transaction handle */
  serpent_init(MAIL_BOX,ILL_FILE);
  transaction = start_transaction();
  commit_transaction(transaction);
  serpent_cleanup();
}
```

**Example 4-1 Sending Transactions**

**Specification Steps:**

1. Declare *transaction variable*. A local variable of transaction_type can be used to maintain a transaction handle.
Modifying Information

2. **Start a transaction.** The `start_transaction` function returns a transaction handle that must be passed to any subsequent commands operating on the transaction.

3. **Commit the transaction.** The actual change to shared data does not occur until the transaction is committed. Up to this point it is also possible to roll back the transaction using the `rollback_transaction` routine so that none of the changes to shared data occur.

### 4.2 Adding Static Information

This section makes some simplifying assumptions about the application that may in fact hold true for simple programs. The primary assumption is that the application will create only a fixed number of shared data instances so that the IDs of these instances can be maintained in local variables. A secondary assumption is that the application will create no more than one instance of each shared data element.

At any given moment, there can be up to three different versions of any given shared data instance. First, there is a local copy in the application. Second, there can be a copy that is part of an open transaction. Third, there is a copy in the shared database. Depending upon whether the shared data instance has been last modified by the application or by the end-user, the more current copy could be either the local application or shared database copy. A shared data instance that is part of an open transaction is the delta from the more current to less current copy of the shared data instance. The shared data copy being affected by any given operation should be apparent from the context.

Variables of generated shared data types are referred to as shared data variables. The first step in adding information to shared data is to assign values to these shared data variables. The method for doing this is based on the Serpent types of the components and is explained in detail in Section 3.2. These variables can then be used to initialize a record instance, either a component at a time or the entire record at once.

Once a transaction has been started, you can begin to add, change or remove information to/from the shared database as part of this transaction. These changes are made as part of the transaction and are not applied to the shared database until the transaction is committed.
The code segment from the spider application in Example 4-2 illustrates the operations involved in adding information to the shared database. Code and comments directly related to the task are emphasized in bold type.

```c
#include "serpent.h" /* serpent interface definition */
#include "spiderA.h" /* application data structures */
#define GREEN_STATUS 0
#define YELLOW_STATUS 1
#define RED_STATUS 2

main() {

  transaction_type transaction; /* transaction handle */
  cc_sdd cc;
  /* shared data variables */
  sensor_sdd gs;
  /* shared data variables */
  id_type id;
  /* object instances */

  serpent_init(MAIL_BOX, ILL_FILE);
  /*
  ** Initialize shared data variables.
  */
  strcpy(cc.name, "CMC");
  cc.status = GREEN_STATUS;

  gs.status = RED_STATUS;
  /*
  ** Start a transaction to be sent to the dialogue.
  */
  transaction = start_transaction();
  /*
  ** Create an instance of the correlation center shared data
  ** record in the transaction and initialize using the shared
  ** data variable.
  */
  id = add_shared_data(
    transaction, "correlation_center", NULL, &cc
  );
  /*
  ** Create an instance of the sensor shared data record but
  ** this time update only the name component.
  */
  gs_id = add_shared_data(
    transaction, "sensor", "name", &gs
  );

  commit_transaction(transaction);

  serpent_cleanup();
}
```

Example 4-2  Adding Information to the Shared Database

**Specification Steps:**

1. **Include Saddle generated header file.** This file (spiderA.h in the example) defines the structure of the shared data. The file serpent.h must be included before spiderA.h because spidera.h uses types defined in serpent.h.
2. **Define constants.** The spider example contains three constants: `GREEN_STATUS`, `YELLOW_STATUS`, and `RED_STATUS`. These constants are not required but help increase the clarity of the example.

3. **Define shared data variables.** Variables `cmc` and `gs1` are both instances of generated shared data structures. These variables are used to initialize instances of shared data in the shared database.

   The variables `cmc_id` and `gs1_id` are used to store the ids of the created shared data instances. These variables are declared to be of `id_type`. The ids are necessary to perform further operations on these instances in the shared database.

4. **Assign values to shared data variables.** The mechanism for accomplishing this task depends on the component types. This is explained in detail in Section 3.2.

5. **Add information to the shared database.** The `add_shared_data` routine creates a shared data instance as part of the specified transaction and returns the ID of the instance. The routine allows you to initialize a single component of the instance by specifying the name of the component and providing a pointer to the initial value. Any uninitialized fields of the instance are left undefined. It is also possible to initialize the entire instance by providing a pointer to the structure and specifying NULL for the component name.

### 4.3 Adding Dynamic Information

In larger, more complex software systems it is not always practical to declare a fixed collection of variables to represent data. The management of dynamically created data structures is often radically different from that of static variables. The purpose of this section is to reexamine how the application can create and manage shared data in this more complex environment. To do this, the spider chart example has been modified to display $n$ sensors, where $n$ is defined in an external file along with the sensor data.

The code segment from the spider application in Example 4-3 illustrates the operations involved in adding dynamic information to the shared database. Code and comments directly related to the task are emphasized in bold type.

```c
#include "serpent.h"  /* serpent interface definition */
#include "spiderA.h"  /* application data structures */

main() {
    transaction_type transaction;
    HASH id_table; /* hash of id’s of all shared data in view */
    sensor_sdd *sensor;
    FILE *fp;      /* file pointer to the data file */
    int i = 0;    /* counter used for loading sensors */
    int sensor_count; /* number of sensors */
```
serpent_init(MAIL_BOX, ILL_FILE);

/*
** Create an id hashtable. This table contains the ids of all the shared data instances in the shared database at any given time.
*/

id_table = make_hashtable(
    MAX_HASH, sss_hash_id, sss_match_id);

/*
** Start a transaction.
*/

transaction = start_transaction();

/*
** Sensor data is stored in an external file.
*/

fp = fopen("sdata", "r");

/*
** The first field in the file contains the number of sensors.
*/

fscanf(fp, "%d", &sensor_count);

/*
** Read in each sensor and put into shared data.
*/

i = 0;

while (i++ < sensor_count) {/* while sensor’s left */

    /*
    ** Create shared data record instance.
    */

    sensor = (sensor_sdd *)make_node(sizeof(sensor_sdd));

    /*
    ** Read in sensor data into shared data record instance.
    ** Note: ‘&’ address operators are omitted from most components because they are arrays and are already passed by reference.
    */

    fscanf(
        fp, "%s%d%s%s%s",
        sensor->site_abbr,
        &sensor->status,
        sensor->site,
        sensor->last_message,
        sensor->rfo,
        sensor->etro
    );

    /*
    ** Put sensor into shared data.
    */

    sensor->self = add_shared_data(
        transaction, "sensor_sdd", NULL, NULL
    );

    put_shared_data(
        transaction, sensor->self, "sensor_sdd", NULL, sensor
    );

    /*
    ** Add shared data instance to id table.
    */

    add_to_hashtable(id_table, sensor, sensor->self);
}

} /* end while file not empty */
** Close the data file.
*/
fclose(fp);
commit_transaction(transaction);
serpent_cleanup();
}

Example 4-3 Adding Information to the Shared Database

Specification Steps:
1. **Add self component to shared data record templates.** The self component is used to store the ID of a shared data instance directly in the shared data structure. This field of the structure is used in the example to identify the particular shared data instance. The self component is of type id. To add this component to the shared data record template, it is necessary to modify the shared data definition file and then repeat the steps described in Section 3.1.

2. **Include Saddle generated header file.** The spiderA.h header file contains the shared data structures for the spider example. This file must be included after serpent.h since serpent_A.h uses types defined in this other file.

3. **Define local variables.** The next preliminary step is to define local variables. The sensor variable declared in Example 4-4 is no longer an instance but a pointer to the sensor_sdd structure. This variable will be used to reference dynamically allocated local instances of the sensor structure.

   The id_table variable is a hash table that is used to store and access local instances of sensor data. The hash table has proven to be a very effective data structure for accomplishing this since the lookup can be done using ID values, which are unique. An implementation of hash tables, as well as other abstract data structures, are included in the C-programmer’s toolkit that is distributed with Serpent.

4. **Create local data structures.** A local shared data instance is created (allocated from memory) for each sensor in the file. These instances are stored in a hash table that must also be created.

5. **Initialize local shared data instances.** Each local shared data value must then be initialized. In Example 4-4, this is accomplished by reading the data directly into the sensor structure from the file.
6. **Add information to the shared database.** Once a transaction has been started and the data initialized, information can be added to the shared database. In Example 4-4, this is a two-step procedure. An uninitialized sensor instance is created with the `add_shared_data` function. The resulting id is assigned to the `self` component of the local shared data instance. The sensor instance is then initialized using the `put_shared_data` procedure that behaves much like the `add_shared_data` function but operates on an existing shared data instance.

7. **Update the local database.** The last step is to add the local shared data instance to the hash table using the ID of the shared data instance. This ID can later be used as an identifier in updating changes to shared data in local data.

### 4.4 Modifying Information

Shared data instances in transactions or in the shared database can be modified using the `put_shared_data` procedure. This procedure takes as a parameter the ID of the shared data instance.

It is possible to modify any single component of a shared data record instance, or the entire record. Unmodified components in the transaction are marked as unchanged and maintain their current values. This is different from components that are explicitly set to undefined, which is actually a value.

The code segment from the spider application in Example 4-4 illustrates the operations involved in adding dynamic information to the shared database. Code and comments directly related to the task are emphasized in bold type.

```c
#include "serpent.h"  /* serpent interface definition */
#include "spiderA.h"  /* application data structures */

main() {
    transaction_type transaction;
    sensor_sdd gs1;  /* shared data variables */
    id_type cmc_id,gs1_id;  /* object instances */

    serpent_init(MAIL_BOX,ILL_FILE);
    transaction = start_transaction();
    /*
    ** Update the name component of the sensor using a
    ** string constant.
    */
    put_shared_data(
        transaction, gs1_id, "sensor", "status", "GS1"
```
Modifying Information

};
commit_transaction(transaction);
serpent_cleanup();
}

Example 4-4  Modifying Information in the Shared Database

Specification Task

Modifying information in the shared database. The `put_shared_data` routine modifies the values of shared data instances that have already been created and are part of a transaction. This routine works in an identical manner to the `add_shared_data` call except that it takes an extra parameter, the ID of the shared data instance to be modified. The `put_shared_data` routine in Example 4-5 is used to assign a value (a string) to the name component of the first shared data instance.

4.5 Removing Information

Shared data instances in transactions or in the shared database can be removed using the `remove_shared_data` procedure. It is not possible to remove components of shared data record instances.

The code segment from the spider application in Example 4-5 illustrates the operations involved in removing information from the shared database. Code and comments directly related to the task are emphasized in bold type.

```c
#include "serpent.h" /* serpent interface definition */
#include "spiderA.h" /* application data structures */

main() {
    transaction_type transaction;
    sensor_sdd gs1; /* shared data variables */
    id_type cmc_id,gs1_id; /* object instances */
    serpent_init(MAIL_BOX,ILL_FILE);
    transaction = start_transaction();
    /*
     ** Update the name component of the sensor using a
     ** string constant.
     */
    remove_shared_data(transaction, "sensor_sdd", gs1_id);
    commit_transaction(transaction);
    serpent_cleanup();
}

Example 4-5  Removing Information from the Shared Database
Specification Task

Removing information from the shared database. The `remove_shared_data` procedure is used to remove a shared data instance from either the transaction or the shared database. The procedure takes a transaction handle, the element name, and the ID of the shared data instance to be deleted as parameters.
5 Retrieving Information

Serpent implements an *active database model* from the perspective of the application interface. This means that changes to application data resulting from end-user interactions with the system are automatically communicated back to the application, using the same transaction mechanism described in Section 4.3.

Transactions from the dialogue to the application consist of a list of changed shared data instances. The following assumptions are true about incoming transactions:

- Incoming transactions are guaranteed to have at least one changed shared data instance since empty transactions are automatically discarded by the interface.
- Changed shared data elements appear in random order in the transaction.
- Transactions remain unmodified in memory until the transaction is purged. This allows the application developer, for example, to reexamine changed instances.

5.1 Retrieving Transactions

The code segment from the spider application shown in Example 5-3 illustrates the basic operations of retrieving information from the shared database.

**Specification Steps:**

1. *Get the transaction.* The Serpent interface provides both synchronous and asynchronous calls for getting information from the shared database. The `get_transaction` routine waits until a transaction is available and then returns a handle for this transaction. The `get_transaction_no_wait` routine returns `not_available` when no transaction is available.

2. *Get each changed shared data instance.* The `get_first_changed_element` routine returns the first changed shared data element instance in the transaction and marks it as the *current* element. The `get_next_changed_element` routine returns the element directly following the current element and marks it as current. The `null_id` is returned if there is no next element instance on the list.

3. *Purge the transaction.* Once the transaction has been fully processed, it should be purged from the system. This frees system resources that could otherwise run out.

Code and comments directly related to the task are emphasized in bold type.
main() {
    boolean done = false;
    id_type id;
    transaction_type transaction;
    serpent_init(MAIL_BOX, ILL_FILE);
    :
    /*
    ** Retrieve information from shared database.
    */
    while (!done) {
        transaction = get_transaction()
        id = get_first_changed_element(transaction);
        /*
        ** Get each changed instance in the transaction.
        */
        while (id != null_id) {
            id = get_next_changed_element(transaction);
        }
        purge_transaction(transaction);
    }
    return();
}

Example 5-1  Transaction Processing

5.2 Incorporating Changes

Changed element instances from the dialogue need to be processed for any changes in the application domain to be affected. The Serpent application interface provides several routines for the purpose of processing changed shared data elements.

This section makes some simplifying assumptions about the application that may in fact hold true for simple programs. The primary assumption is that the application has created only a fixed number of shared data instances so that the IDs of these instances can be maintained as static, local variables. A secondary assumption is that the application has created no more than one instance of each shared data record.

The code segment from the spider application in Example 5-2 illustrates the operations involved in incorporating changes to shared data elements in static, local variables. Code and comments directly related to the task are emphasized in bold type.

main() {
    id_type id;
    transaction_type transaction;
    string element_name;
    :
id = get_first_changed_element(transaction);
/*
** Get each changed record instance in the transaction.
*/
while (id != null_id) {
    element_name = get_element_name(transaction, id);
    /*
    ** If the record is a correlation center then this must
    ** be the cmc shared data variable.
    */
    if (strcmp(element_name, "cc_sdd") == 0) {
        incorporate_changes(transaction, id, &cmc);
    }
    /*
    ** Otherwise, this must be the gsl variable.
    */
    else {
        incorporate_changes(transaction, id, &gsl);
    }
    id = get_next_changed_element(transaction);
}
return();

Example 5-2  Processing Changes to Shared Data Records (Simple Programs)

Specification Steps:
1. Get the element name. This is a simple call that returns a pointer to the element name. For simple programs that have no more than one instance of a particular shared data record, the element name can be used to identify the shared data instance. In larger, more complex systems it is often useful in determining a class of shared data instances.

2. Update local database. Shared data variables can be updated using the incorporate_changes routine. This routine directly incorporates changes in the shared data instance into the local variable. Components of the shared data record that have not been changed are left untouched. By continually incorporating changes into the initial shared data variable, the application developer is guaranteed that application data remains consistent with user input.

5.3 Processing Dynamic Elements

In larger systems, it is often necessary to dynamically create shared data records, or instantiate multiple instances of a single shared data record. This section describes how changed shared data record instances can be managed in these situations.
In the dialogue, it is also possible to create, modify, or remove instances of application shared data as a result of input from the end user. This is known as the change type. Each shared data record instance in a transaction has an associated change type.

These steps are illustrated in Example 5-3 taken from the spider chart example. Code and comments directly related to the task are emphasized in bold type.

```c
main() {
    id_type id;
    transaction_type transaction;
    sensor_sdd *sensor;

    change_type change;
    : 
      id = get_first_changed_element(transaction);
    /*
    ** Get each changed record instance in the transaction.
    */
      while (id != null_id) {
        change = get_change_type(transaction, id);
        /*
        ** Update the local database based on the change type.
        */
        switch(change) {
          case create:
            sensor = get_shared_data(transaction, id, NULL);
            add_to_hashtable(id_table, sensor, id);
            break;
          case modify:
            sensor = get_from_hashtable(id_table, id);
            incorporate_changes(transaction, id, sensor);
            break;
          case remove:
            sensor = delete_from_hashtable(id_table, id);
            free(sensor);
            break;
        }
      } /* end switch */

      id = get_next_changed_element(transaction);
    }
}

return();
```

Example 5-3   Processing Changes to Shared Data Records (Large Systems)

**Specification Steps:**

1. **Determine the change type.** The change type can be obtained using the `get_change_type` function.
2. **Update the local database based on the change type.** The exact type of processing required to update the local database is based primarily on the change type. If this is a new shared data element (e.g., the change type is `create`) the `get_shared_data` function can be used to create a copy of the record instance. The memory required for this copy is automatically allocated from process memory using the `make_node` function provided in the C Toolkit memoryPack utility distributed with Serpent. This copy can then be added to the hash table.

If the change type is `modify`, the local shared data instance can be obtained from the hash table. The `incorporate_changes` routine can then be used to update the contents of this instance with changed component values.

If the shared data record instance in the shared database has been deleted, the application developer may want to delete it from the local database as well. Memory allocated by the `get_shared_data` function should be freed using the `free_node` procedure provided in the C Toolkit memoryPack utility.

### 5.4 Examining Changes by Component

The Serpent application programmer’s interface provides routines that allow the application developer to examine each changed component in a changed record individually.

The operations are illustrated in Example 5-4, taken from the spider chart example. Code and comments directly related to the task are emphasized in bold type.

```c
main() {
    id_type id;
    transaction_type transaction;
    sensor_sdd sensor;
    string element_name;

    serpent_data_types type;
    id_type *id_data;
    string component_name;
    LIST changed_components;

    id = get_first_changed_element(transaction);
    /*
     ** Get each changed record instance recording the transaction.
     */
    while (id != null_id) {
        changed_components = create_changed_component_list(
            transaction, id
        );
```
loop_through_list(
    changed_components, component_name, string
) {
    type = get_shared_data_type(
        element_name, component_name
    );
    if (type == serpent_id) {
        id_data = (id_type *)get_shared_data(
            transaction, id, component_name
        );
    } /* endif id type */
} /* end loop through list */
free_list(changed_components, NOT_NODES);

return();

Example 5-4  Processing Changes to Shared Data Records (Large Systems)

Specification Steps:
1. **Get the list of changed components.** A list of changed components can be obtained by using the create_changed_component_list function.
2. **Loop through the list.** The listPack contained in the C toolkit distributed with Serpent provides a number of routines that can be used for processing the elements on a list.
3. **Examine the type and/or data.** The Serpent application programmer’s interface provides routines to examine both the type and the data at the component level. The get_shared_data_type returns a serpent_data_type. The get_shared_data routine can also be used to return the component value instead of the element instance value by specifying the name of a component. Serpent automatically allocates the storage for the component value but it is the application programmer’s responsibility to free this storage (using the free_node procedure available in the C toolkit memoryPack).
4. **Destroy the changed component list.** The changed component list can be destroyed using the free_list routine from the C toolkit listPack.
6 Finishing the Application

Other than sending and retrieving data, the application can determine errors from the use of Serpent, record communication between the application and Serpent and exit according to a signal received from the dialogue.

6.1 Error Checking

Each routine in Serpent sets status on exit. It is good software engineering practice to check status after every call to make sure that the routine has executed correctly, and provide appropriate recovery actions if it has not. Example 6-1 illustrates the routines provided by Serpent for examining the status.

```c
transaction = start_transaction();
if(get_status() != ok) {
    print_status("error during start_transaction");
    serpent_cleanup();
}
```

**Example 6-1 Examining Status**

The first of these routines is `get_status`, which returns an enumeration of status codes. Valid statuses returned by each routine in Serpent are defined in Appendix B. Successful execution (or “OK”) is always set to zero; hence, it is possible to make a simple boolean comparison for bad status.

The `print_status` routine prints a user-defined error message and the current status.

6.2 Recording Transactions

Transactions between the application and the dialogue can be recorded using the `start_recording` and `stop_recording` procedures available in the Serpent application programmers interface. After the call to `start_recording` is made, transactions may be sent across the interface. Any number of transactions containing any type or amount of data can be sent. Once `start_recording` has been called, all transactions and associated data will be written to the specified file until the `stop_recording` routine is invoked.

Transactions can be examined using the `format` command described in Section 7.1. This is useful in debugging since it allows the examination of information flow across the interface. Transactions can also be played back to simulate either application or dialogue functionality using the `playback` command described in Section 7.2.
Before testing the application or the dialogue, first record the transactions to be used in testing. Example 6-2 illustrates the basic operations for recording transactions.

```c
transaction_type transaction;

/*
** Start recording.
*/
start_recording("recording", "test data: 5.7.3");

/*
** Send test data.
*/
transaction = start_transaction();
commit_transaction(transaction);
transaction = start_transaction();
commit_transaction(transaction);
transaction = start_transaction();
commit_transaction(transaction);

/*
** Stop recording.
*/
stop_recording();
}
```

**Example 6-2  Recording Transactions**

**Specification Steps:**

1. **Start recording.** The `start_recording` routine takes as parameters both the name of the file in which to save the recording and a message to help identify the recording.
2. **Send transactions.** After the call to `start_recording` is made, transactions may be sent across the interface.
3. **Stop recording.** The `stop_recording` function closes the current recording file.

### 6.3 Dialogue Initiated Exit

The dialogue can terminate at any time using the `exit` command available to the dialogue specifier. The `exit` command sends a SIGINT signal to the application. This signal will cause the application to exit immediately, unless a signal handler has been registered with the operating system.
Finishing the Application

The signal handler describes the steps to be taken when the dialogue initiates an exit. Typically, this involves saving data structures out to permanent storage and exiting the system.

The code segment in Example 6-3 taken from the spider chart illustrates the operations necessary to handle dialogue initiated exit. Code and comments directly related to the task are emphasized in bold type.

```c
#include <signal.h>                     /* UNIX signal handling */

void spider_signal_handler()
{
    serpent_cleanup();
    exit (0);
}

main ()
{
    signal(SIGINT, spider_signal_handler);
    serpent_init(MAIL_BOX, ILL_FILE);
    serpent_cleanup();
}
```

Example 6-3  Signal Handler for Dialogue Initiated Exit

Specification Steps:

1. **Include Unix signal handling.** The `signal.h` include file contains the external definitions for signal processing.

2. **Write the signal handler.** The signal handler describes the steps to be taken when the dialogue initiates an exit. Remember to invoke `serpent_cleanup` before exiting.

3. **Register the signal handler.** The signal handler must be associated with the `SIGINT` signal. This is accomplished using the Unix `signal` function.
7 Testing and Debugging

The recording capability discussed in Chapter 3 provides a mechanism to assist in testing and debugging.

7.1 Formatting Recordings

Application recordings are saved in a binary format file. The format command distributed with Serpent converts this file into a formatted, easy-to-read report. The information in the file can be useful in isolating problems to either the application or the dialogue.

```
% format recording
FORMATTING JOURNAL FILE: recording

HEADER:
   dialogue name:
   message: no comment at this time

OWNER:
   ill file name: se.ill
   mailbox name: SE_BOX

PARTICIPANT:
   ill file name: se.ill
   mailbox name: DM_BOX

TRANSACTION:
   Sender: SE_BOX
   Receiver: DM_BOX

Element name: dialogue_sdd Change type: create ID: 955
   shared_data            buffer     UNDEFINED_BUFFER
   termination            buffer     UNDEFINED_BUFFER
   macros                 buffer     UNDEFINED_BUFFER
   externs                buffer     UNDEFINED_BUFFER
   initialization         buffer     UNDEFINED_BUFFER
   count                  integer    0
   name                   string     UNDEFINED_STRING
   prologue               buffer     UNDEFINED_BUFFER
```

Example 7-1  Formatting the Recording File
7.2 Playback

Once you have made a recording, it is possible play back the recording to simulate one or more of the Serpent processes. To simulate the spider application, for example, you would run the `playback` command provided with Serpent specifying the name of the recording file and the mailbox of the process to be simulated, as illustrated in Example 7-2.

```
% app-test recording SPIDERA_BOX
Playing back journal file: recording
Message: regression test data, 5.7.3
Playback completed successfully
%
```

Example 7-2  Testing the Application
Appendix A  Data Structures

This appendix presents in alphabetical order the type and constant definitions that are used in the C language interface to the Serpent system. The following is a list and short description of each of these types and constants. A more complete description immediately follows:

<table>
<thead>
<tr>
<th>Type/Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>buffer</td>
<td>used to define the structure of a shared data buffer</td>
</tr>
<tr>
<td>change_type</td>
<td>defines the type of modification made for an element</td>
</tr>
<tr>
<td>id_type</td>
<td>used to uniquely identify shared data elements</td>
</tr>
<tr>
<td>null_id</td>
<td>defines the null value for the id_type</td>
</tr>
<tr>
<td>serpent_data_types</td>
<td>an enumeration of defined Serpent data types</td>
</tr>
<tr>
<td>transaction_type</td>
<td>used to define transaction handles</td>
</tr>
</tbody>
</table>
TYPE

buffer

Description
The buffer type allows the communication of $n$ bytes of application data along with an indication of the type. Buffer is the only dynamic shared data type in that neither the size nor the type of the information is predefined. Buffers can be used to: share untyped, contiguous data; share large amounts of contiguous data (i.e., large strings); provide variant records.

Definition
```c
typedef struct {
    int length;
    caddr_t body;
    serpent_data_type type;
} buffer;
```

Components

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>length</td>
<td>Size in bytes of the data. This field is required even if the data is of a well known type (i.e., integer).</td>
</tr>
<tr>
<td>body</td>
<td>A pointer to the actual data. The space used to maintain this data is not part of the buffer structure and must be managed by the user.</td>
</tr>
<tr>
<td>type</td>
<td>The type of information stored in the buffer. This field is also required.</td>
</tr>
</tbody>
</table>
TYPE

change_type

Description
The change_type defines the type of modification made for an element.

Definition
```c
typedef enum change_type {
    no_change = -1,
    create = 0,
    modify = 1,
    remove = 2,
    get = 3
} change_type;
```

Components
- no_change: Not changed or invalid change.
- remove: Existing shared data instance removed.
- create: New shared data instance created.
- modify: Existing shared data instance modified.
- remove: Existing shared data instance removed.
Data Structures

**TYPE**

<table>
<thead>
<tr>
<th>id_type</th>
</tr>
</thead>
</table>

**Description**  
The `id_type` is used to uniquely identify shared data elements.

**Definition**  
`typedef private id_type;`
## null_id

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>null_id</code> constant defines the null value for the <code>id_type</code>. This constant can be used to test for null ID values.</th>
</tr>

TYPE

transaction_type

| Description       | Variables of transaction_type are used to define transactions. |
Appendix B  Routines

This appendix presents in alphabetical order the functions and procedures that make up the C language interface to Serpent. These routines can be categorized as follows:

Initialization/Cleanup
- serpent_init
- serpent_cleanup

Transaction Processing
- start_transaction
- commit_transaction
- rollback_transaction
- get_transaction
- get_transaction_no_wait
- purge_transaction

Sending and Retrieving Data
- add_shared_data
- put_shared_data
- remove_shared_data
- get_first_changed_element
- get_next_changed_element
- get_shared_data
- incorporate_changes
- create_changed_component_list
- get_change_type
- get_element_name
- get_shared_data_type

Undefined Values
- set_undefined
- is_undefined

Record/Playback
- start_recording
- stop_recording
Routines

Checking Status

- get_status
- print_status
FUNCTION

add_shared_data

Description
The add_shared_data routine creates an instance for the specified shared data element and returns a unique ID. The shared data instance may or may not be initialized.

Syntax
id_type add_shared_data(
    /* transaction : in transaction_type */
    /* element_name : in string */
    /* component_name : in string */
    /* data : in caddr_t */
);

Parameters
- transaction: The transaction for which this operation is defined.
- element_name: The name of the shared data element.
- component_name: The name of a specific component to be initialized with the data, or null if the data corresponds to the entire element.
- data: Data or null pointer if non-initialized.

Returns
The ID of the newly created shared data instance.

Status
ok, out_of_memory, null_element_name, overflow
commit_transaction

**Description**
The `commit_transaction` procedure is used to commit a transaction to the shared database.

**Syntax**
```c
void commit_transaction(
    /* transaction: in transaction_type */
);
```

**Parameters**
- `transaction` Existing transaction ID.

**Status**
- ok, out_of_memory, invalid_transaction_handle
FUNCTION

create_changed_component_list

Description
The `create_changed_component_list` function accepts an instance ID as a parameter and creates a list of changed component names. This component list is managed using the C Toolkit listPack distributed with Serpent.

Syntax
```c
LIST create_changed_component_list(
    /* id: in id_type */
);
```

Parameters
- `id` Existing data instance ID.

Returns
The list of changed component names associated with a data instance, or NULL if none.

Status
- `ok`, `invalid_id`, `out_of_memory`, `element_not_a_record`
FUNCTION

get_change_type

Description
The get_change_type function accepts an instance ID as a parameter and returns the associated change type.

Syntax
change_type get_change_type(
   /* id : in id_type */
);

Parameters
id
Existing shared data ID.

Returns
Element name associated with the shared data instance ID.

Status
ok, invalid_change_type, invalid_transaction_handle, invalid_id
Routines

FUNCTION

get_element_name

<table>
<thead>
<tr>
<th>Description</th>
<th>The get_element_name function accepts an instance ID as a parameter and returns the associated element name.</th>
</tr>
</thead>
</table>
| Syntax      | string get_element_name(  
|             |     /* id : in id_type */  
|             | );                                                                                             |
| Parameters  | id Existing shared data ID.                                                                      |
| Returns     | Element name associated with the shared data instance ID.                                       |
| Status      | ok, invalid_id                                                                                  |
FUNCTION

## get_first_changed_element

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>get_first_changed_element</code> function used to get the ID of the first changed element in a transaction.</th>
</tr>
</thead>
</table>
| Syntax      | `id_type get_first_changed_element(
  /* transaction_type : in transaction */
);`                                                                                           |
| Parameters  | `transaction` Existing transaction ID.                                                      |
| Returns     | The handle of the first changed element.                                                    |
| Status      | `ok, invalid_transaction_handle, out_of_memory`                                              |
### get_next_changed_element

**Description**  
The `get_next_changed_element` function is used to get the ID of the next changed element on a transaction list or return `null_id` if the transaction list is empty.

**Syntax**  
```
id_type get_next_changed_element(
    /* transaction_type : in transaction */
);
```

**Parameters**  
- `transaction`: Existing transaction ID.

**Returns**  
The handle of the next changed element.

**Status**  
- `ok`, `invalid_transaction_handle`, `out_of_memory`
## get_shared_data

**Description**  
The get_shared_data function allocates process memory, copies shared data into process memory, and returns a pointer to the data.

*Warning:* Record components may not have been specified and, therefore, would not contain valid data.

**Syntax**
```c
caddr_t get_shared_data(
    /* transaction : in transaction_type */
    /* id : in id_type */
    /* component_name : in string */
);
```

**Parameters**
- `transaction`  
  Transaction in which to find the shared data ID.
- `id`  
  Existing shared data ID.
- `component_name`  
  Name of component for which to retrieve data, or entire element if NULL.

**Returns**  
A pointer to changed data.

**Status**  
ok, invalid_id, out_of_memory, incomplete_record
FUNCTION

**get_shared_data_type**

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>get_shared_data_type</code> function is used to get the type associated with a shared data element.</th>
</tr>
</thead>
</table>
| Syntax      | `serpent_data_types get_shared_data_type(
               /* element_name: in string */
               /* component_name: in string */
               );` |
| Parameters  | *element_name* The name of the shared data element.                                              |
|             | *component_name* The name of the shared data component, or NULL.                                 |
| Returns     | The type of the shared data element or record component.                                         |
| Status      | `ok, null_element_name`                                                                          |
Routines

FUNCTION

---

**get_status**

---

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>get_status</code> function returns the current system status.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>isc_status get_status();</code></td>
</tr>
<tr>
<td>Parameters</td>
<td>None.</td>
</tr>
<tr>
<td>Returns</td>
<td>The current status.</td>
</tr>
<tr>
<td>Status</td>
<td>None.</td>
</tr>
</tbody>
</table>
### get_transaction

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>get_transaction</code> function is used to synchronously retrieve the ID for the next completed transaction.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>transaction_type get_transaction();</code></td>
</tr>
<tr>
<td>Parameters</td>
<td>None.</td>
</tr>
<tr>
<td>Returns</td>
<td>The transaction ID for a completed transaction.</td>
</tr>
<tr>
<td>Status</td>
<td><code>ok, system_operation_failed</code></td>
</tr>
</tbody>
</table>
**FUNCTION**

## get_transaction_no_wait

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>get_transaction</code> function is used to asynchronously retrieve the ID for the next completed transaction.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>transaction_type get_transaction_no_wait();</code></td>
</tr>
<tr>
<td>Parameters</td>
<td>None.</td>
</tr>
<tr>
<td>Returns</td>
<td>The transaction ID for a completed transaction.</td>
</tr>
<tr>
<td>Status</td>
<td><code>ok, system_operation_failed, not_available</code></td>
</tr>
</tbody>
</table>
PROCEDURE

incorporate_changes

**Description**
The `incorporate_changes` procedure is used to incorporate changes into local process memory without destroying unchanged information.

**Syntax**
```c
void incorporate_changes(
    /* transaction : in transaction_type */
    /* id : in id_type */
    /* data : in out caddr_t */
);
```

**Parameters**
- **transaction**: Existing transaction ID.
- **id**: Existing shared data ID.
- **data**: Pointer to the local data structure to be updated.

**Status**
- ok, invalid_id
## is_undefined

**Description**  
The `is_undefined` function evaluates a data value of a specified type and determines if the value is undefined. The `is_undefined` function cannot be used with an entire shared data record at once.

**Syntax**  
```c
boolean is_undefined(  
    /* type : in serpent_data_type */
    /* data : in caddr_t */
);
```

**Parameters**  
- **type**  
The type of the shared data component.
- **data**  
Pointer to the value being examined.

**Returns**  
True if data is undefined; false otherwise.

**Status**  
`ok, operation_undefined_type`
## print_status

### Description
The `print_status` procedure prints out a user-defined error message and the current status.

### Syntax
```c
void print_status(
    /* error_msg : in string */
);
```

### Parameters
- **error_msg**: User-defined error message.

### Status
None.
PROCEDURE

purge_transaction

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>purge_transaction</code> procedure is used to remove a received transaction once the contents of the transaction have been examined and acted upon.</th>
</tr>
</thead>
</table>
| Syntax              | `void purge_transaction(
  /* transaction : in transaction_type */
);`                                                                                                                                 |
| Parameters          | `transaction` Existing transaction ID.                                                                                                                                                     |
| Status              | `ok, invalid_id, illegal_receiver`                                                                                                                                                         |
Routines

PROCEDURE

put_shared_data

Description
The put_shared_data call is used to put information into shared data.

Syntax

```c
void put_shared_data(
    /* transaction : in transaction_type */
    /* id : in id_type */
    /* element_name : in string */
    /* component_name : in string */
    /* data : in caddr_t */
);
```

Parameters

- `transaction`: The transaction to which the shared data should be put.
- `id`: Shared data ID.
- `element_name`: The name of the shared data element.
- `component_name`: The name of the shared data component.
- `data`: Shared data.

Status

- `ok`, `undefined_shared_data_type`, `null_element_name`, `invalid_id`
PROCEDURE

### remove_shared_data

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>remove_shared_data</code> procedure is used to remove a specified shared data instance from the shared database.</th>
</tr>
</thead>
</table>
| Syntax      | `void remove_shared_data(`\* transaction : in transaction_type*/
|             | `/* element_name : in string */
|             | `/* id : in id_type */
|             | `)`;                                                                                           |
| Parameters  | **transaction** Transaction from which to remove the shared data element.                        |
|             | **element_name** Name of element to be removed.                                                  |
|             | **id** Existing shared data ID.                                                                  |
| Status      | **ok, out_of_memory, null_element_name, invalid_id**                                             |
Routines

PROCEDURE

rollback_transaction

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>rollback_transaction</code> procedure is used to abort a given transaction and to delete the associated transaction buffer.</th>
</tr>
</thead>
</table>
| Syntax      | void rollback_transaction(  
|             |    /* transaction : in transaction_type */  
|             |    );                                                                                                           |
| Parameters  | transaction               Existing transaction ID.                                                                 |
| Returns     | A handle to a newly-created element                                                                               |
| Status      | `ok, invalid_transaction_handle`                                                                               |
PROCEDURE

serpent_init

Description
The serpent_init procedure performs necessary initialization of the interface layer.

Syntax
void serpent_init(
    /* mailbox : in string */
    /* ill_file : in string */
);

Parameters
- mailbox: MAIL_BOX constant defined in Saddle-generated include file.
- ill_file: ILL_FILE constant defined in Saddle-generated include file.

Status
ok, out_of_memory, null_mailbox_name, null_ill_file_name, system_operation_failed
Routines

PROCEDURE

**serpent_cleanup**

<table>
<thead>
<tr>
<th>Description</th>
<th>The <em>serpent_cleanup</em> procedure performs necessary cleanup of the interface layer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>void serpent_cleanup();</code></td>
</tr>
<tr>
<td>Parameters</td>
<td>None.</td>
</tr>
<tr>
<td>Status</td>
<td><code>ok</code></td>
</tr>
</tbody>
</table>
Routines

PROCEDURE

set_undefined

Description The set_undefined procedure sets the value of the data pointed to by value to undefined. The set_undefined procedure cannot be used with an entire shared data record at once.

Syntax

```c
void set_undefined(
    /* type : in serpent_data_type */
    /* data : in caddr_t */
);
```

Parameters

- **type**: The type of the shared data component.
- **data**: Pointer to the value being set to undefined.

Status

- ok, operation_undefined_type
## PROCEDURE

### start_recording

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>start_recording</code> procedure enables recording. Once <code>start_recording</code> has been called, all transactions and associated data will be saved out to the specified file until the <code>stop_recording</code> procedure is invoked.</th>
</tr>
</thead>
</table>
| Syntax      | `void start_recording(
    /* file_name : in string */
    /* message : in string */
);` |
| Parameters  | `file_name`  File to which to write recording.  |
|            | `message`    Recording description.    |
| Status      | `ok, io_failure, already_recording` |
**FUNCTION**

**start_transaction**

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>start_transaction</code> function is used to define the start of a series of shared data modifications.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>transaction_type start_transaction();</code></td>
</tr>
<tr>
<td>Parameters</td>
<td>None.</td>
</tr>
<tr>
<td>Returns</td>
<td>A unique transaction ID.</td>
</tr>
<tr>
<td>Status</td>
<td><code>ok, out_of_memory, overflow</code></td>
</tr>
</tbody>
</table>
## PROCEDURE

### stop_recording

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>stop_recording</code> procedure causes the current recording to be stopped.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>void stop_recording();</code></td>
</tr>
<tr>
<td>Parameters</td>
<td>None.</td>
</tr>
<tr>
<td>Status</td>
<td><code>ok, io_failure, invalid_process_record</code></td>
</tr>
</tbody>
</table>
Appendix C  Commands for Testing Serpent Applications and Dialogues

This appendix contains definitions of commands provided with Serpent to assist in testing Serpent applications and dialogues. The following is a list and short description of each of these commands. A more complete description immediately follows:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
<td>converts a recording file into an easy-to-read report</td>
</tr>
<tr>
<td>playback</td>
<td>used to play back a recording file</td>
</tr>
</tbody>
</table>
Commands for Testing Serpent Applications and Dialogues
### COMMAND

#### format

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>format</code> command converts a binary Serpent transaction log to a formatted, easy-to-read report. The report is written to standards output.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Definition</td>
<td><code>format recfile</code></td>
</tr>
</tbody>
</table>
| Parameters        | `recfile`  
The transaction log to be converted.                                                                                       |
| Returns           | 0  
`ok`                                                                                                                            |
**playback**

**COMMAND**

<table>
<thead>
<tr>
<th>Description</th>
<th>The <code>playback</code> command can be used to reenact a session based on a recording file.</th>

### Title
Serpent: C Application Developer's Guide

### Abstract
Serpent is a user interface management system (UIMS) that supports the development and implementation of user interfaces, providing an editor to specify the user interface and a runtime system that enables communication between the application and the end user. This manual describes how to develop applications using Serpent. Readers are assumed to have read and understood the concepts described in the Serpent Overview, as well as to have had experience using the C programming language.
